Table of contents

1	Overview	1
2	Age Distribution	1
3	Restricted Mean Survival Comparison	2
4	Interpretation	2

1 Overview

This technical note evaluates how population averaging over observed ages affects survival predictions for the single joint economic model. The comparison holds all patients at the mean observed age while retaining their observed sex and biomarker values.

2 Age Distribution

Table 1: Age distribution in the economic survival complete-case data

Metric	Value
Patients	68
Mean age	64.4
Median age	65.0
Minimum age	38.0
Maximum age	80.0

3 Restricted Mean Survival Comparison

Table 2: Restricted mean survival under observed-age and mean-age predictions

Strategy	Endpoint	Base Case Years	Mean-Age Years	Difference
Standard of Care	Overall survival	2.313	2.311	-0.002
Standard of Care	Progression-free survival	0.987	0.987	-0.000
CRP-guided	Overall survival	2.156	2.155	-0.002
CRP-guided	Progression-free survival	1.412	1.411	-0.001
TMB/BRAF-guided	Overall survival	2.159	2.157	-0.002
TMB/BRAF-guided	Progression-free survival	1.171	1.169	-0.001

Figure 1: Observed-age and mean-age survival predictions

4 Interpretation

The base case averages predictions over the observed age distribution. The mean-age scenario is a diagnostic check that removes age heterogeneity while keeping the same fitted survival model and strategy definitions.
